

ABSTRACT

1 An exemplary system includes a browser to browse a web page based on a
2 web page definition having a slicing tree defining an arrangement of rectangular
3 regions in the web page. The web page definition can include parametric data
4 describing adaptability parameters associated with a rectangular region. A
5 rendering module renders an adapted web page based on the web page definition,
6 and a proxy module generates an intermediary adapted web page definition. A
7 method includes rendering the web page according to a slicing tree and block
8 property data in an associated web page definition. The method may include
9 determining a set of unsummarized blocks that maximize information fidelity.
